

Assignment : 06

Ganesh Gundekarla

Here , my student login EUID is : gg0640

So , $n+1 = 0+1 = 1$ = Chi-Square Test if $n+1=1, 5, 9$

Step 1 : Imported the required libraries .

Here I had imported stats library present in scipy module

For visualization , we had imported matplotlib.pyplot which is built matplotlib.

Step 02:

Here “ `variable = np.linspace( 0 , 20,100)` “

This function `linspace()` from numpy , this enables us in creating arrays matrices and some functions which are related to mathematics.

- a. Linspace is used to create an array of even spaced numbers or values of a specified interval.
- b. `0,20,100` : this condition in `linspace` creates us values from 0 to 20 which 100 points in between them .
- c. This allows you to have some range of values to work with .

Step 03:

`degrees_of_freedom = [1, 4, 6, 7]`

Here , these are the values here that are allowed to vary very freely . so this each degree of freedom value corresponds us to a specific scenario in our tests .

So , if we are having a table with 2 rows and 2 tables dataset , the degrees of freedom would be

Degrees of freedom = (rows num -1) * (columns number -1)

Which is $(2-1)*(2-1) = 1$.

Which results in a specific scenario .

Step 04 :

`plt.figure(figsize=(10, 6))`

This is basically done to create a visualization plot in the output which the given size and it is done using matplotlib in python .

The syntax is `figure(figsize=(width,height))` which plots according to the user given ratios.

Step 05:

In step 05 we basically iterated over the degrees of freedom which is done using the for loop .

- a. So by iterating it and then the plotting of corresponding chi square with the probability density is done . This basically means that that this allow us to visualize how the shape of the chi test is being altered with application to different degrees of freedom
- b. So , here for each of the value for degrees of freedom , it calculates the pdf for the chi squared using the .pdf() function imported from the stats module and then it plots the pdf against the variable using plot .
- c. Then the `plt.plot(variable , chi_sq_pdf,label=f'df={df}')` :The plotting is done here with the chi squared values are being plotted against pdf values , a label argument is also allowed in the pdf() function which indicates the degrees of freedom as a label on the plot .

Step 06 :

Plotting :

Then the plotted graph is further enhanced. Here , the title and the x and y labels are being plotted .

Here , we can choose to display the legend , by using `plt.legend()` we can display the legend on the plot which takes the labels from the for loop including the degrees of freedom .

We can also choose to have the grid in the plot or not . This can be done by using the `plt.grid(False)` this takes Boolean value true or false to display the grid or not .

`Plt.show()` : this element is used to display the plot which is configured above and this is the must step to display the plot .

Code

```
# my student login id is gg0640
# so n= 0
# 0+1= 1 : chi-Squared test
from scipy import stats # importing libraries for stats and maths and
visualization
```

```

import numpy as np
import matplotlib.pyplot as plt
variable = np.linspace(0, 20, 100) # Generating values from 0 to 20 with 100
underlying points
degrees_of_freedom = [1, 4, 6, 7] # Different degrees of freedom ranging from
1,7
print(variable)
plt.figure(figsize=(10, 6)) # Setting figure size of the plotting size
for df in degrees_of_freedom: # iterating over a for loop with deg of freedom
    chi_sq_pdf = stats.chi2.pdf(variable, df) # pdf for chi squared using pdf
function
    plt.plot(variable, chi_sq_pdf, label=f'df={df}') # plotting
plt.title('Chi-Square test')
plt.xlabel('Values on x axis ')
plt.ylabel('Density')
plt.legend()
plt.grid(False)
plt.show()

```

The screenshot shows a Google Colab notebook titled 'chisquaredtest1.ipynb'. The code is as follows:

```

[5] # my student login id is gg0640
    # so n= 0
    # 0+1= 1 : chi-Squared test

[6] from scipy import stats
    import numpy as np
    import matplotlib.pyplot as plt

[7] variable = np.linspace(0, 20, 100) # Generating values from 0 to 20
    degrees_of_freedom = [1, 4, 6, 7] # Different degrees of freedom ranging from 1,7
    print(variable)

[8] plt.figure(figsize=(10, 6)) # Setting figure size

```

The output of the code is a list of 100 values generated by `np.linspace(0, 20, 100)`, displayed in a single line across multiple columns. The values range from 0.0 to 20.0 in increments of 0.2.
